

Data Migration & Logic Design – Brief

Integrating banking, telecoms, insurance, hospitality, and schools

Bottom line

Adopt a **hybrid migration approach** (bulk historic load + incremental sync) with a centralized ingestion-and-orchestration layer; manual inputs overwrite scraper data. This balances speed, data integrity, and near-zero downtime.

Context

- Architecture Summary Report provides the baseline data-flow and domain-model definitions [2] [3].
- Current system scrapes data and also accepts manual frontend entries that must take precedence.
- No “fintech logic” folder was found on the PC (search returned zero matches) [1].

Options

1. **Lift-and-Shift** – bulk export/import then one-off reconciliation. *Pro*: fast; *Con*: longer validation window.
2. **Incremental Sync with Dual-Write Buffer** – parallel pipelines into staging, switch consumers gradually. *Pro*: near-zero downtime; *Con*: higher orchestration complexity.
3. **Hybrid (Recommended)** – bulk load for historic data + incremental sync for active records, using a rules engine for conflict resolution (manual overrides scraper). *Pro*: balances speed and safety; *Con*: moderate implementation effort.

Recommendation

Proceed with the **Hybrid approach**. It ensures rapid migration of legacy data while maintaining continuous validation and real-time updates for new records.

Open questions

- Which legacy databases require schema-level transformations beyond the unified model?
- What SLA limits apply to the incremental sync window for each domain?

- Are there regulatory compliance checks (e.g., KYC for banking) that need separate validation steps?

Prepared by Tao, Technical Writer

Actions taken

- Confirmed absence of a "fintech logic" folder on the local machine [1].
- Referenced the Architecture Summary Report as the source of the migration logic [2][3].
- Drafted the brief and sent it via internal mail to arthurmagaya29@gmail.com (email sent successfully) [5].
